Agenda

Why do we need a Web of Things?
What are its main objectives?

Information processing in the Web of Things

A Data-centric Web of Things

Device management in the Web of Things

MOTIVATION

Internet of Things and the Web of Things

Things are proxies for physical, real-world objects on the Internet

WoT

Assessing the things via
standard Web technologies

Internet of Things and **The Web of Things**

Things are proxies for physical, real-world
objects on the Internet

Web of Things Objectives

Web of Things is an application layer for the IoT – with the main objectives:

- Discovery
- Identification
- Integration into platforms
- Interpretation of information
- Interoperability across platforms
- Security and privacy

Use Case: Digital Twins

Virtual representation of a (group of) devices on an edge or cloud server

Useful to simulate new configurations or services prior to deployment

Usable proxy, even if real-world devices are offline

Accessible from the public Internet, even if the devices are not

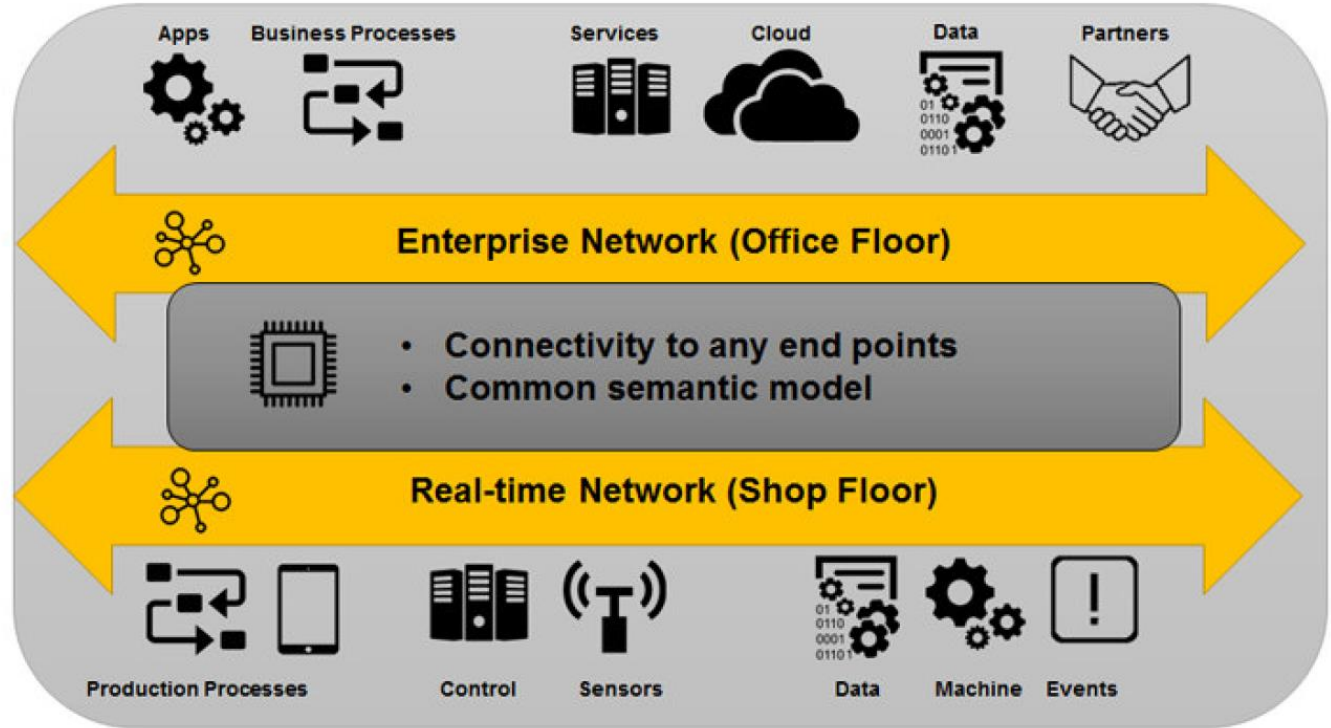

Source: <https://www.w3.org/TR/wot-architecture/images/wot-use-cases/digital-twin.svg>

Integration Use Case: Industrie 4.0

IT - Information
Technology Level

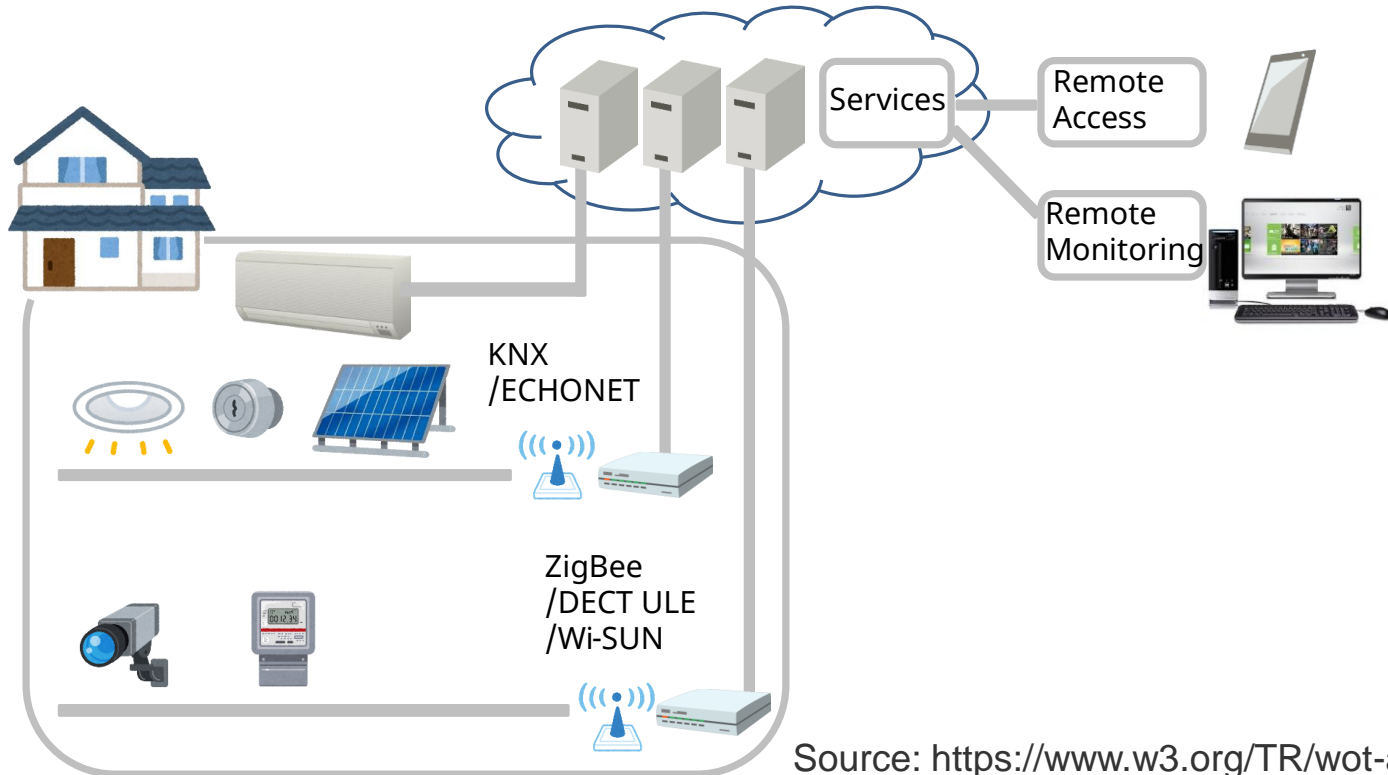

Integration

OT - Operational
Technology Level

WoT Requirements

Interoperability - must be possible to connect a WoT enabled device with a cloud service from different manufacturers out of the box

Compatibility – must bridge between existing and developing IoT solutions including upwards compatibility with current standards

Flexibility – shall cover a wide variety of device configurations and IoT implementations

Scalability - must scale for IoT solutions that incorporate thousands to millions of devices

WoT Requirements

The WoT shall enable mutual interworking of different IoT ecosystems using Web technologies and RESTful APIs

Interoperability - must be possible to connect a WoT enabled device with a cloud service from different manufacturers out of the box

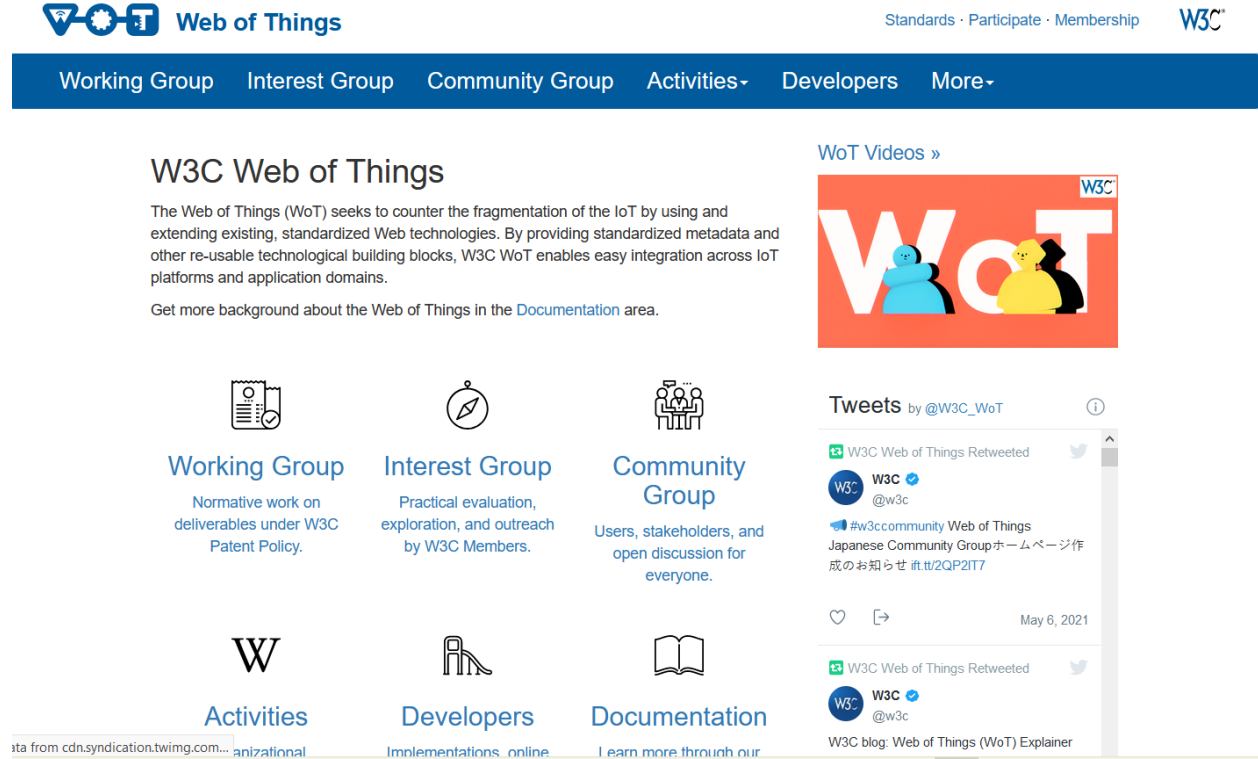

Compatibility – must bridge between existing and developing IoT solutions including upwards compatibility with current standards

Flexibility – shall cover a wide variety of device configurations and IoT implementations

Scalability - must scale for IoT solutions that incorporate thousands to millions of devices

W3C Initiative

<https://www.w3.org/WoT/>

The screenshot shows the W3C Web of Things website. At the top, there is a navigation bar with the 'Web of Things' logo and links for 'Standards', 'Participate', 'Membership', and 'W3C'. Below this is a dark blue menu bar with options: 'Working Group', 'Interest Group', 'Community Group', 'Activities', 'Developers', and 'More'. The main content area features a heading 'W3C Web of Things' followed by a paragraph explaining the initiative's goal to counter IoT fragmentation. A link to the 'Documentation' area is provided. To the right, there is a 'WoT Videos' section with a video thumbnail. Below the main text, there are six icons representing different areas: Working Group (document with checklist), Interest Group (compass), Community Group (group of people), Activities (large 'W'), Developers (hand with mouse), and Documentation (open book). A 'Tweets' section on the right shows a tweet from @w3c about the Japanese Community Group home page.

W3C Web of Things

The Web of Things (WoT) seeks to counter the fragmentation of the IoT by using and extending existing, standardized Web technologies. By providing standardized metadata and other re-usable technological building blocks, W3C WoT enables easy integration across IoT platforms and application domains.

INFORMATION PROCESSING

WoT Information

Information is
addressable by
URIs in the
WoT

Unlock IoT fragmentation by describing

- Properties: Values, configurations, results
- Actions: Operations to perform
- Events: Triggered state changes

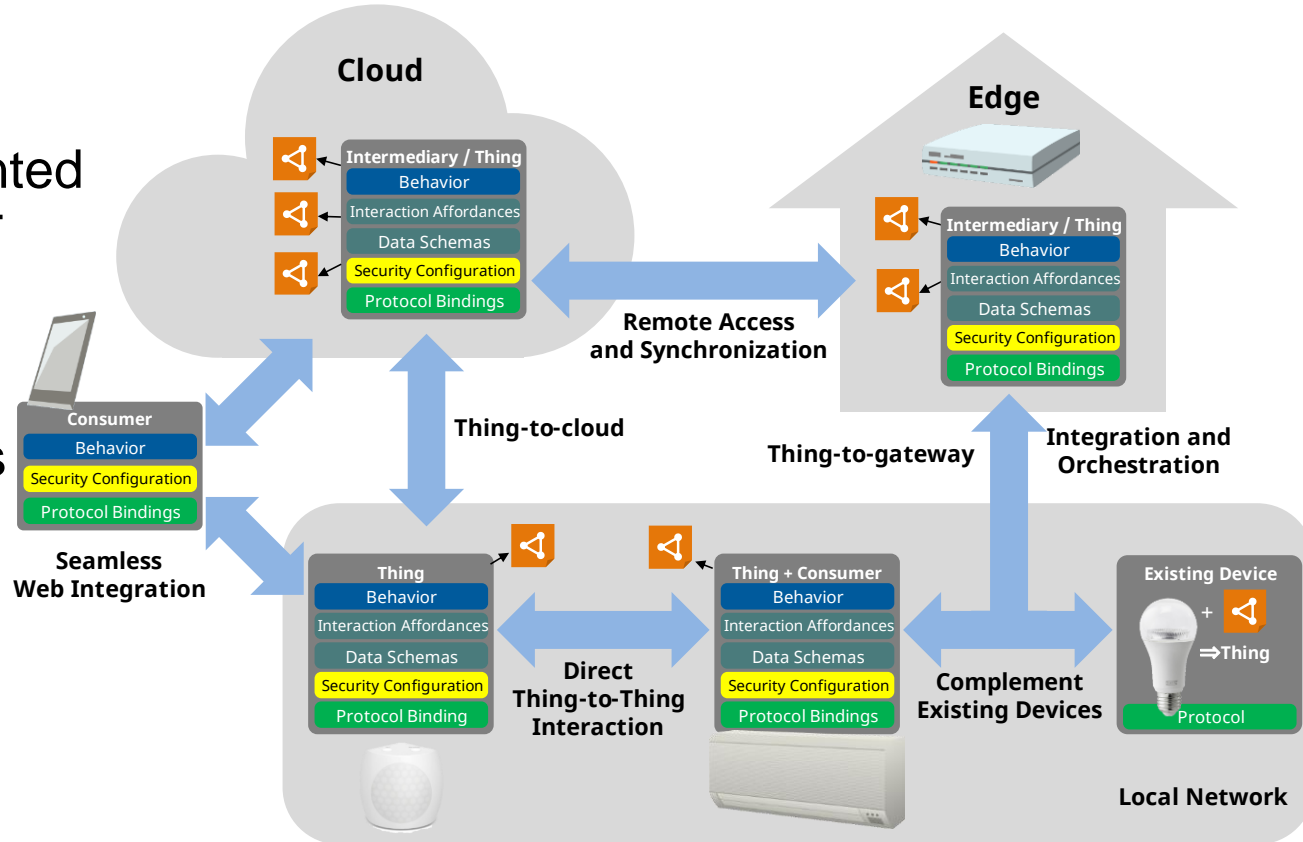

Information is structured in

- Description of Things
- Protocol bindings
- Scripting API
- Security and Privacy

WoT Abstract Architecture

Entities are represented by processable WoT Things Descriptions

This enables various integration patterns s. a. Thing-to-Thing, Thing-to-Gateway, Thing-to-Cloud, etc.

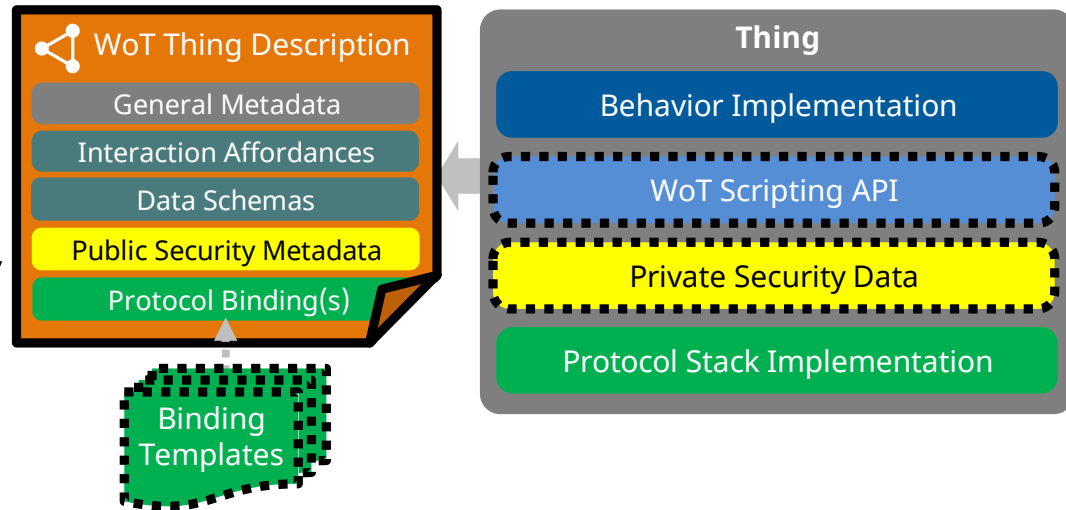

WoT Relationship with a Thing

Things Descriptions (TD)

- Semantic information model: Meta-data for things, human & machine understandable
- Domain-specific vocabulary required (not specified)
- JSON serialization

TD is the “**index.html**” of things in the WoT

Source: <https://www.w3.org/TR/wot-architecture/>

Data Models and Encodings

Description models of specific domains

Various models from diverse bodies:

- SenML (RFC 8428)
- OCF (various appliances)
- OMA (sensor devices)
- IPSO (smart sensors)
- Bluetooth (smart sensors & lighting)
- Zigbee (energy systems & sensors)
- ...

Generic encodings: JSON, CBOR, XML

HOW STANDARDS PROLIFERATE: (SEE: A/C CHARGERS, CHARACTER ENCODINGS, INSTANT MESSAGING, ETC.)

Source: <https://xkcd.com/>

One Data Model

Problem: lack of common IoT data models

Goal: arrive at a common set of data and interaction models that describe IoT devices.

Liaison initiative between IoT organizations

- Creates Semantic Definition Format (SDF)
- Evaluate candidate data models
- Select a single model per function
- Defines a single application data model

Semantic Definition Format (SDF)

Format for creating and maintaining domain specific data and interaction models

Defines Objects, their associated interactions (e.g., Events, Actions, Properties) and data types

Language definition in JSON

- Binding to CBOR/CDDL ([RFC8610](#))
- Further bindings optional

IETF WG ASDF: draft-ietf-asdf-sdf

SDF Example: Switch

```
"sdfObject": {  
  "Switch": {  
    "sdfProperty": {  
      "value": {  
        "description": "The state of the switch; false for off and true for on."  
        "type": "boolean"      } .. },  
    "sdfAction": {  
      "on": {  
        "description": "Turn the switch on; equivalent to setting value to true."  
      },  
      "off": {  
        "description": "Turn the switch off; equivalent to setting value to false."  
      },  
      "toggle": {  
        "description": "Toggle the switch; equivalent to setting value to its complement."      } ... }  
    }  
  }  
}
```

DATA-CENTRIC WOT

How to Best Access Content in the WoT?

Problems with End-to-End data delivery

- Constrained devices shielded by gateways
- Transcoding gateways break E2E security
- Multi-hop forwarding in lossy regimes
- Changing paths by link flux and mobility

Alternative transport concepts

- Information-centric data replication
- WoT relies on REST access by CoAP

Lessons Learned from **Information Centric Networking**

Performance Boosts from 10 Years of Research

**Adaptive
Forwarding**

**In-network
Caching**

**Content Object
Security**

Adaptive forwarding and **caching** shorten request paths and reduce link traversals on retransmissions

Content object security enables end-to-end security and reduces session management complexity

- Asynchronous Multi-Fanout
- RESTful Access with CoAP

Making IoT Content Cacheable

OSCORE protects CoAP messages providing integrity, authenticity, and confidentiality on an object level

CoAP messages are encapsulated as an authenticated and encrypted COSE object

OSCORE makes its objects transport-agnostics and is able to secure multicast messages

OSCORE Integration in CoAP

Forwarding OSCORE Content Objects w/ Proxies

Cacheability

- Strong response binding prevents cache hits for subsequent requests
- **Use retransmission caches to recover messages of same transaction**

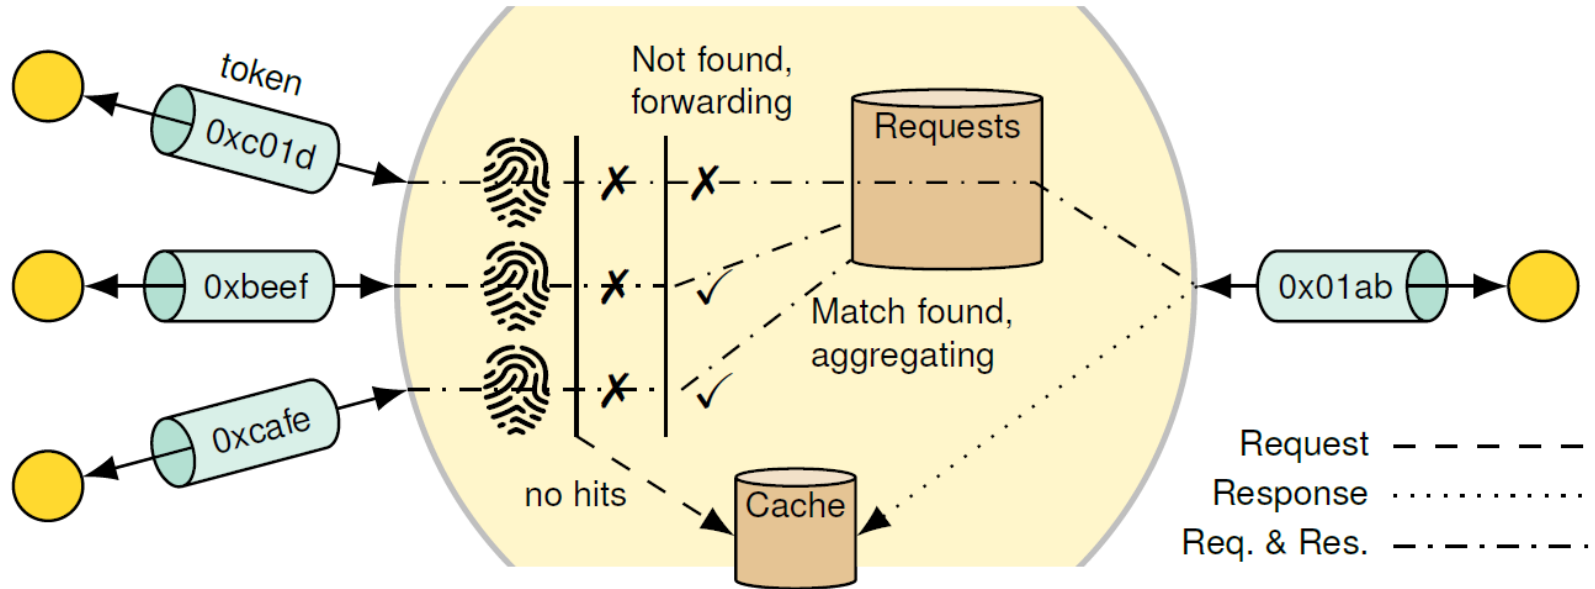

Proxy on each forwarding node

- OSCORE Objects cached
- Hop-wise message timeout
- Retransmissions on each forwarder

Decoupling of data from location

- Link-local IP addressing
- Forwarding via resource name

Forwarding and Caching with CoAP Proxy

Constructing a Data-Centric Web of Things

Communication Model & Flow Control

- CoAP GET method provides request-response paradigm
- Acknowledgments for requests and optionally for responses

Adaptive Forwarding & Caching

- CoAP proxies forward requests and build reverse path
- Proxies cache incoming responses

Content Object Security

- OSCORE provides authenticated encryption
- End-to-end security persists across gateways

Performance Evaluation in a Testbed

ABSTRACT

The information-centric networking (ICN) paradigm offers replication of autonomously verifiable content throughout a network, in which content is bound to names instead of hosts. This has proven beneficial in particular for the constrained IoT. Several approaches, the most prominent of which being Named Data Networking, propose access to named content directly on the network layer. Independently, the IETF CoAP protocol group started to develop mechanisms that support autonomous content processing and in-network storage.

In this paper, we explore the emerging CoAP protocol building blocks and how they contribute to an information-centric network architecture for a data-oriented RESTful Web of Things. We discuss design options and measure characteristic performances of different network configurations, which deploy CoAP proxies and OSCORE content object security, and compare with NDN. Our findings indicate an almost continuous design space ranging from plain CoAP at the one end to NDN on the other. On both ends—ICN and CoAP—we identify protocol features and aspects whose mutual transfer potentially improves design and operation of the other.

1 INTRODUCTION

More than a decade ago Information-Centric Networking (ICN) [5, 61] introduced the idea to turn named content objects into first class citizens of the Internet ecosystem. This new paradigm gave rise to (i) a decoupling of content from hosts and thus the ability of ubiquitous content caching [4] without a clumsy, closed CDN (Content Delivery Network) infrastructure, and (ii) serverless routing on names without the DNS infrastructure [21]; (iii) Named Data Networking (NDN) [28, 62] additionally abandoned network endpoint addresses in favor of a stateful forwarding fabric. These properties enable an asynchronous, hop-by-hop content fetching, which prevents forwarding of unwanted data. The latter significantly reduces the attack surface of (Distributed) Denial-of-Service (DDoS).

All three constituents make ICN appealing to the (constrained) Internet of Things (IoT) as infrastructural burdens and common DDoS threats, which have established in the current Internet, stand in the way of a lean and efficient inter-networking for embedded devices. Early experimental work [12, 37] could indeed show that NDN can successfully operate on very constrained nodes with noticeable resource savings compared to IP. In addition, short-term in-network caching proved valuable for increasing reliability in low power lossy networks with nodes frequently at sleep as common at the IoT edge [23, 26].

Since that time, the Internet of Things is gaining momentum and its deployment is driven by industrial needs [25]. These needs are served by the protocol interfaces available from cloud providers—predominantly MQTT [13] (such as Amazon AWS)—or by the IETF IoT protocol suite centered around the Constrained Application Protocol (CoAP) [52]. The CoAP protocol group (CoRE) has recently developed a rich set of additional features, which open various deployment options—content object security and in-network caching are among them.

In this paper, we explore the emerging building blocks of the CoAP protocol suite to answer the question: *Can we build a restful*

DEVICE MANAGEMENT

Management Problem

In the IoT, large numbers of devices require the following management tasks:

- Bootstrapping
- Device identification & registration
- Firmware updates
- Fault management
- Configuration & control
- Reporting

Management Integration Platforms

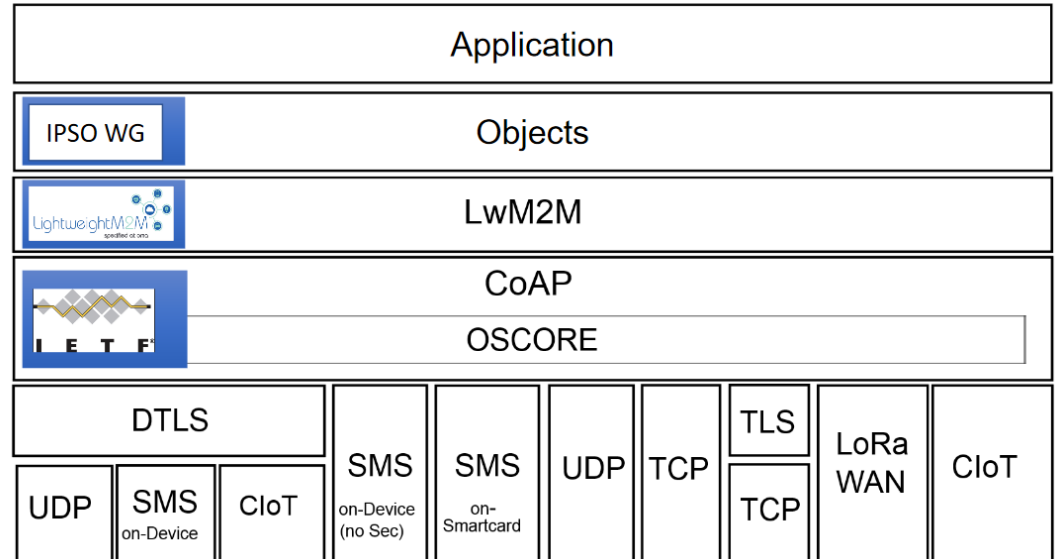

Several platforms for integrated management exist

- Watson IoT, Thingsware, Fiware, AWS IoT Mgmt, ..

LwM2M optimized for constrained IoT (< 20 kB M)

- OpenMobileAlliance
- Integrated with IETF stack

LwM2M Protocol stack

LwM2M Architecture

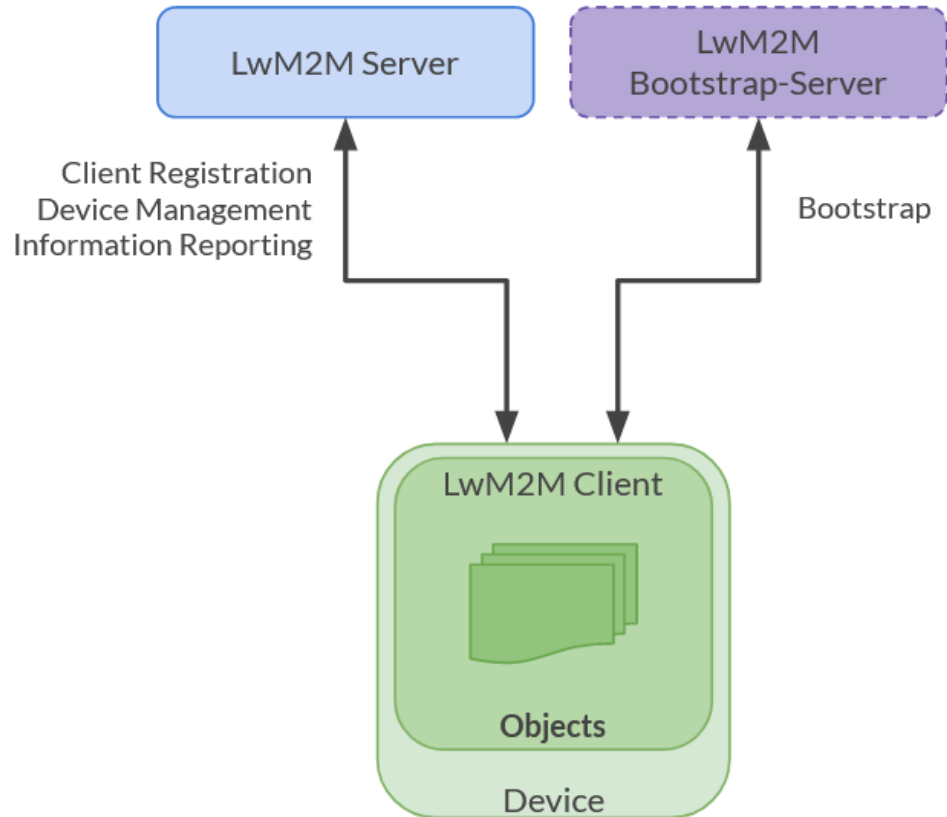

Bootstrap process

- Access Control Lists are installed
- Server credentials and information are installed

Client registers itself to the server.

The server may operate on the client's resources.

Access control is done **locally** by the client, upon installation of access rules.

Operations on LwM2M Objects

All operations are performed on resources of object instances

Objects' and resources' schemas placed in “OMA LwM2M Object and Resource Registry”

Access is controlled via Access Control Object instances associated to servers. Example: read the boolean input of a presence sensor:

GET coaps://[fd00:c0de::1234]/3302/1/5500

- Method for a Read operation in CoAP binding
- Authority
- Object ID
- Instance 1 (many sensors may be hosted)
- Digital Input State resource of the instance

Resumé

LwM2M is a lean, popular management approach to constrained IoT devices

Resources are easily accessible via simple CoAP requests from a **preconfigured server**

LwM2M does not define an interface to **request a server access** to a resource

LwM2M does not define an **interface between clients** to operate on resources
